Introduction

The purpose of this book is to teach students of social science statistics courses how to program in R for data analysis. Primarily focusing on Base R, this book will teach R "from the ground up," teaching the fundamentals without using external packages unless necessary or for quick demonstrations on the programming language's extensions. Overall, I hope that students will learn enough from this book to conduct data analysis in R independently.

Because I know people live busy lives, please feel free to skip chapters or simply only review the *Summary* subsections at the end of them—they are for your benefit!

Also, please feel free to email me at robertschnitman@gmail.com if you have any suggestions on improving this book!

8 CONTENTS

Prerequisites

This book assumes that you have installed at least R version 3.6 at minimum (https://cran.r-project.org/). Installing the R Studio IDE afterward is strongly recommended (https://rstudio.com/products/rstudio/). Additionally, the focus of this book is more on programming in R rather than going in depth with the statistics—please consult your statistics textbook for the latter purpose instead.

10 CONTENTS

Chapter 1

The Paradigms of R

There are three main programming paradigms—or styles—that R uses: Array Programming (AP), Functional Programming, and Object Oriented (OOP). Knowing how these paradigms work is important, as they will help one understand the syntax structure of R.

1.1 Array

The Array Programming (AP) paradigm allows us to access elements in a dataset via a matrix-like syntax. This paradigm can be useful when you want a more granular, so to speak, way of subsetting data, as you are able to specify the numeric positions of the desired rows and columns.

```
# Select the 2nd row and 5th column
   from mtcars, which is a pre-loaded dataset.
mtcars[2, 5]
## [1] 3.9
# Select the first 5 rows and all columns
mtcars[1:5, ]
##
                      mpg cyl disp hp drat
                                               wt qsec vs am gear carb
## Mazda RX4
                               160 110 3.90 2.620 16.46
                     21.0
                                                         0
## Mazda RX4 Wag
                     21.0
                            6 160 110 3.90 2.875 17.02
                     22.8
                               108 93 3.85 2.320 18.61
## Datsun 710
                                                                      1
## Hornet 4 Drive
                     21.4
                               258 110 3.08 3.215 19.44
                                                                      1
## Hornet Sportabout 18.7
                               360 175 3.15 3.440 17.02 0 0
                                                                      2
```

8

1.2 Functional

Much like Excel, R has functions: execution statements with an input and an output—this syntax style is called Functional Programming (FP). The benefit of FP is that we can think more at a "high level": we simply input some data, and the function processes it without our stating of *how* we want to execute the information. In other words, we can treat functions as "black boxes" that output our desired result based on our specified inputs.

Below is an example of using the mean() function to calculate the average miles per gallon from the mtcars dataset.

```
# Mean of MPG from the mtcars dataset
# Input = mtcars$mpg
# OUtput = numeric value
mean(mtcars$mpg) # $ accesses MPG from mtcars.
```

```
## [1] 20.09062
```

Just like in math and Excel, we can compose multiple functions together.

```
# Rounding the mean MPG by 2 digits.
round(mean(mtcars$mpg), 2)
```

[1] 20.09

1.3 Object Oriented

In R, we can create and access objects, which are a storage of information with attributes: this paradigm is called Object Oriented Programming (OOP), which is concerned about classes and types—the "foreground" and "background" characteristics of a dataset, so to speak. Classes affect how data look to the user, whereas types are the specific attributes of some data.

Classes and types are discussed in the Basics chapter.

```
# Access the MPG variable from mtcars
# and save it to an object named "x"
x <- mtcars$mpg

# We can now refer to mtcars$mpg anytime with "x"
x

## [1] 21.0 21.0 22.8 21.4 18.7 18.1 14.3 24.4 22.8 19.2 17.8 16.4 17.3 15.2 10.4
## [16] 10.4 14.7 32.4 30.4 33.9 21.5 15.5 15.2 13.3 19.2 27.3 26.0 30.4 15.8 19.7
## [31] 15.0 21.4
```

We can check the structure of our data objects to know their attributes.

1.4. SUMMARY 13

```
# Check the structure of mtcars.
# A data frame composed of numeric vectors.
str(mtcars)

## 'data.frame': 32 obs. of 11 variables:
## $ mpg : num 21 21 22.8 21.4 18.7 18.1 14.3 24.4 22.8 19.2 ...
## $ cyl : num 6 6 4 6 8 6 8 4 4 6 ...
## $ disp: num 160 160 108 258 360 ...
## $ hp : num 110 110 93 110 175 105 245 62 95 123 ...
## $ drat: num 3.9 3.9 3.85 3.08 3.15 2.76 3.21 3.69 3.92 3.92 ...
## $ wt : num 2.62 2.88 2.32 3.21 3.44 ...
## $ qsec: num 16.5 17 18.6 19.4 17 ...
## $ vs : num 0 0 1 1 0 1 0 1 1 1 ...
## $ am : num 1 1 1 0 0 0 0 0 0 0 ...
## $ gear: num 4 4 4 3 3 3 3 4 4 4 ...
## $ carb: num 4 4 1 1 2 1 4 2 2 4 ...
```

1.4 Summary

Table 1.1: Summary of Paradigms

Paradigm	Description	Example
Array	Bracket syntax	mtcars[2, 5]
	structure to access data like a matrix	
Functional	Mathematical function	mean(mtcars\$mpg)
	syntax structure to compute over data.	
Object Oriented	Syntax structure in which data has stored attributes that affect how they look to the user.	str(mtcars)

Chapter 2

Basics

In this chapter, we will learn how to use R as a calculator; learn the different data types and classes in R; learn how to make assignments; and learn how to get help when you are stuck on a particular issue.

2.1 R as a calculator

You can use R like a calculator: the arithmetic operators are +, -, *, /, $^{^{\circ}}$ (exponentiation), and % (modular arithmetic)—there are more, but these operators are the basic ones (see more by typing ?'+' into your console).

2.1.1 Operators

```
2+2  # Addition

## [1] 4

2-2  # Subtraction

## [1] 0

2*2  # Multiplication

## [1] 4

2/2  # Division

## [1] 1

2^2  # Exponentiation

## [1] 4
```

2%%2 # Modular arithmetic

[1] 0

2.2 Data Types and Classes

Classes are the "foreground" and types are the "background" characteristics of data. Classes affect how data look to the user, whereas types are the specific attributes of some data. We can check the class of an object with the class() function and type with the typeof() function.

Additionally, we can test to see if some data are a particular class or type with the is.*() and convert them with as.*(), where * can represent the classes and types that follow.

2.2.1 Classes

There are many classes—some pre-defined in R, while others have been created externally. The three main classes (besides the numeric and character vector class, which are also types) are the matrix, list, and data frame.

Type	Decsription	Example
matrix	A 2-dimensional array of elements, where each column is of the same	matrix(1:9, 3, 3)
list	A collection of elements, where each one can be a different type or class.	list(1, "a", matrix(1:9, 3, 3)
data frame	A 2-dimensional set of elements, where each column can be a different type.	mtcars

Table 2.1: Summary of Classes

2.2.2 Types

2.3 Assignments

Making assignments in R allows us to save information into an object, which further allows us to refer to a specific value without having to recalculate it each time.

Type Decsription Example numeric A vector of numbers. "String" A vector of strings (i.e. character characters encased in quotes. Value of TRUE or TRUE logical FALSE. factor A categorical vector factor(mtcars\$am) with specified levels.

Table 2.2: Summary of Types

```
x <- 2
x
```

[1] 2

For a more complex example, we will run a regression model, save it to an object, and pass it to the summary() function to get more information from our model besides just its coefficients—we'll learn more about regressions in the *Linear Modeling* chapter.

```
my_model <- lm(mpg ~ wt + hp + am, mtcars)
summary(my_model)</pre>
```

```
##
## Call:
## lm(formula = mpg ~ wt + hp + am, data = mtcars)
##
## Residuals:
##
       Min
                1Q Median
                                3Q
                                       Max
## -3.4221 -1.7924 -0.3788 1.2249
##
## Coefficients:
                Estimate Std. Error t value Pr(>|t|)
##
## (Intercept) 34.002875
                           2.642659 12.867 2.82e-13 ***
                                    -3.181 0.003574 **
## wt
               -2.878575
                           0.904971
               -0.037479
                           0.009605 -3.902 0.000546 ***
## hp
## am
                2.083710
                           1.376420
                                      1.514 0.141268
## ---
                   0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
## Signif. codes:
## Residual standard error: 2.538 on 28 degrees of freedom
## Multiple R-squared: 0.8399, Adjusted R-squared: 0.8227
```

```
## F-statistic: 48.96 on 3 and 28 DF, p-value: 2.908e-11
```

2.3.1 Adding/Removing Variables

There are two main ways we can add variables to our dataset: (1) the \$ ("accessor"/dollar-sign) method and (2) the transform() method.

```
mydata <- mtcars # copy data

# Let's create a variable called "my_new_var"
mydata$my_new_var <- with(mtcars, mpg/wt)

# Alternatively, the right-hand side
# could be written as mtcars$mpg/mtcars$wt.

# Show a few rows from our dataset
head(mydata)</pre>
```

```
##
                     mpg cyl disp hp drat
                                             wt qsec vs am gear carb my_new_var
## Mazda RX4
                    21.0
                          6 160 110 3.90 2.620 16.46 0 1
                                                              4
                                                                   4
                                                                       8.015267
## Mazda RX4 Wag
                    21.0
                            160 110 3.90 2.875 17.02 0 1
                                                                       7.304348
## Datsun 710
                    22.8
                             108 93 3.85 2.320 18.61 1 1
                                                              4
                                                                       9.827586
                          4
                                                                   1
                                                              3
## Hornet 4 Drive
                    21.4
                          6
                             258 110 3.08 3.215 19.44
                                                      1 0
                                                                   1
                                                                       6.656299
## Hornet Sportabout 18.7
                          8 360 175 3.15 3.440 17.02 0 0
                                                              3
                                                                   2 5.436047
## Valiant
                          6 225 105 2.76 3.460 20.22 1 0
                    18.1

                                                                        1
```

2.4 Viewing Data

We can view data like an Excel spreadsheet in a separate window in R (or separate tab in RStudio) via the View() function. Try it out in your console!

View(mtcars)

2.5 Getting Help

There are two main ways of getting help in R: (1) using the ? operator to access a function's documentation and (2) Googling your questions OR searching for them on StackOverflow—when you're beginning R, chances are that the problems you encounter have been solved.

```
# Accessing the documentation for the mean function. ?mean
```

2.6 Summary

Chapter 3

Data Management

In this chapter, we will learn how to replace values, switch values, import data, combine data, subset data, and split data.

3.1 Replacing Values

We can replace values with the replace() function.

```
x <- 1:10 # 1 through 10.

# If x equals 2, 5, or 7, replace with 0.
## replace(vector, condition, replacement value).
replace(x, x %in% c(2, 5, 7), 0)</pre>
```

[1] 1 0 3 4 0 6 0 8 9 10

3.2 Switching Values

We can switch—or recode—values with the switch() function. By default, switch() is a "scalar" function in that it only produces a single value. To produce a vector of values, we combine it with sapply()—see the Functionals chapter for more details on sapply().

3.2.1 Scalar Case

In the case of a single value, all we need to pass into switch() are (1) the data object and (2) an expression stating what the old value should become (i.e, provide the old value and the replacement value).

```
# SYNTAX OF switch():
## switch(x, old_value = new_value)
```

```
x <- "a"
x
## [1] "a"
xs <- switch(x, a = 1)
xs
## [1] 1</pre>
```

3.2.2 Vector Case

For the case of applying switch() to vectors, we make use of sapply().

To take a case in point, let's first generate some random data of racial groups.

```
set.seed(1) # Remember our random sampling

# Generate vector of unique values.
my_vector <- c('Asian', 'African American', 'White', 'Other')

my_vector</pre>
```

```
## [1] "Asian" "African American" "White" "Other"
# Conduct repeat sampling of my_vector
## See the Probability Functions chapter for more details on sample().
my_vector2 <- sample(my_vector, 20, replace = TRUE)

# Print the new vector.
my_vector2</pre>
```

```
## [1] "Asian" "Other" "White" "Asian" "White" "Asian" "Asian" "African American" "African American" "African American" "White" "White" "African American" "White" "African American" "White" "White" "African American" "White" "White" "African American" "White" "White
```

Let's say that we want to recode these values: 0 for White, 1 for African American, 2 for Asian, and 3 for Other. To do so, we first define a function and pass it through sapply()—see the Function Writing and Functionals chapters respectively for more information.

```
# First, define a function that recodes the races into integers.
my_switch <- function(v) {
   switch(v, White = 0, `African American` = 1, Asian = 2, Other = 3)</pre>
```

```
# We use back quotes for "African American" because of the space.
}

# Now we can pass my_switch to sapply() to execute the recoding.
sapply(my_vector2, my_switch)
```

##		Asian		Other		White		Asian
##		2		3		0		2
##	${\tt African}$	${\tt American}$		Asian		White		White
##		1		2		0		0
##	${\tt African}$	${\tt American}$	${\tt African}$	${\tt American}$		White		White
##		1		1		0		0
##		Asian		Asian		Asian	${\tt African}$	${\tt American}$
##		2		2		2		1
##	${\tt African}$	${\tt American}$	${\tt African}$	${\tt American}$	${\tt African}$	${\tt American}$		White
##		1		1		1		0

3.3 Importing Data

We can import datasets with read.table()-this method is the most general.

```
# Set path to dataset
# For this example, our data is in the data folder
# and our data are separated by commas.
my_data <- read.table('data/mtcars.csv', sep = ',', stringsAsFactors = FALSE)
# Setting stringsAsFactors = FALSE maintains strings as strings.
## See the Basics chapter for more detail on classes and types.</pre>
```

In the case of files with comma-separated values, we can use read.csv() to import them more easily.

```
# Set path to dataset
my_data <- read.csv('data/mtcars.csv', stringsAsFactors = FALSE)</pre>
```

3.4 Combining Data

There are three main ways to combine data: (1) cbind(), (2) rbind(), and (3) merge().

3.4.1 cbind()/rbind()

The function cbind() combines vectors or datasets column-wise, while rbind() does so row-wise.

```
# Creating x and y
x < -1:5
y < -6:10
# Seeing x and y separately
х
## [1] 1 2 3 4 5
## [1] 6 7 8 9 10
# Combining them
cbind(x, y)
##
        х у
## [1,] 1 6
## [2,] 2 7
## [3,] 3 8
## [4,] 4 9
## [5,] 5 10
rbind(x, y)
     [,1] [,2] [,3] [,4] [,5]
##
## x
             2
        1
                  3
             7
## y
        6
                  8
                       9
                           10
```

If we have a list of values we want to combine, we can use do.call() and cbind()/rbind() together. The former iteratively calls a function on a list, which can be useful for combining multiple datasets together. do.call() is a special case of a function called a *functional*, which is a function that takes other functions as inputs—this concept is discussed more in the *Functionals* chapter.

x 1 2 3 4

```
## y 6 7 8 9 10
## z 11 12 13 14 15
```

3.4.2 merge()

Merging data with merge() (AKA "joining data") is powerful, as we can combine disparate datasets that have a common linking variable between them.

```
set.seed(1) # remember our random numbers from rnorm().
data1 <- data.frame(survey_id = 1:5,</pre>
                               = rnorm(5, mean = 15, sd = 5))
                     wage
data1
     survey_id
##
                    wage
## 1
             1 11.86773
## 2
             2 15.91822
## 3
             3 10.82186
## 4
             4 22.97640
## 5
             5 16.64754
data2 <- data.frame(survey_id = 5:1,</pre>
                     experience = rnorm(5, mean = 5, sd = 3))
data2
##
     survey_id experience
## 1
             5
                  2.538595
## 2
             4
                  6.462287
## 3
             3
                  7.214974
## 4
             2
                  6.727344
             1
                  4.083835
## 5
\# merge(first data, second data, by = 'a common variable').
data_merge <- merge(data1, data2, by = 'survey_id')</pre>
data_merge # An "inner-join" of datasets
##
     survey_id
                    wage experience
## 1
             1 11.86773
                           4.083835
## 2
             2 15.91822
                           6.727344
## 3
             3 10.82186
                           7.214974
## 4
             4 22.97640
                           6.462287
## 5
             5 16.64754
                           2.538595
```

What we accomplished here is an *inner join*: a join in which two datasets overlap. See the documentation file for merge() for more information on different types of joins (i.e., type ?merge into the R console).

5

6 7

8

3.5 Subsetting Data

To subset data, we can pass data and relational/logic operators¹ into the subset() function, or we can use the bracket syntax and use the operators there.

The relational operators are the following:

- <, >, <= (less than or equal to), >= (greater than or equal to)
- == (equal to), != (not equal to)

The main logic operators are the following:

- & (and)
- | (or)

3.5.1 Vector Case

Suppose we have the following vector:

```
x < -10:10  # integers from -10 to 10.
   [1] -10 -9
                -8 -7 -6 -5 -4 -3 -2 -1
                                                 0
                                                     1
                                                         2
## [20]
         9 10
Then we can subset like the following:
x[x < 0] # same as subset(x, x < 0)
## [1] -10 -9 -8 -7 -6 -5 -4 -3 -2 -1
x[x > 2 & x < 5]
## [1] 3 4
# We can use functions inside the brackets.
## For example, %in% is a matching function:
   let's use it to subset for only 1 through 5.
x[x %in% 1:5]
## [1] 1 2 3 4 5
```

3.5.2 Data Frame Case

Suppose the dataset mtcars. Then we can subset like the following:

```
subset(mtcars, mpg > 30) # Same as mtcars[mtcars$mpg > 30, ]
```

¹These operators are "binary operators," which compare values (R Documentation, Comparison). See ?Comparison for more information. For logic operators, see ?Logic.

```

                                                                  8
```

Splitting can be useful when you want to apply a function that's contingent on subsets of data. For example, we can split the data and perform a regression model on each of them.

```
# 1. Split dataset by a splitting variable.
my_split <- split(mtcars, mtcars$gear)

# 2. Estimate a regression model based on each subset.
my_models <- lapply(my_split, function(data) lm(mpg ~ wt, data))

# 3. Print the coefficients in a matrix form.
sapply(my_models, coef)

## 3 4 5
## (Intercept) 28.395036 42.492769 42.562784
## wt -3.156854 -6.863478 -8.046336</pre>
```

For more information about lapply() and sapply(), see the *Functionals* chapter; for more information about lm(), see the *Linear Modeling* chapter.

3.7 Summary

3.7. SUMMARY 29

Table 3.1: Summary of Data Management Functions

Function	Description	Example
replace(x, condition, replacement)	Replace a value in a vector based on a	x <- 1:10; replace(x, x %in% c(2, 5, 7), 0)
switch(x, expression)	condition. Switch (recode) values.	x <- 'a'; switch(x, a = 1)
read.table('path/to/file.cs sep = ',')	svImport a dataset.	my_data <- read.table('data/mtcars.cs sep = ',')
$\operatorname{cbind}(x,y)/\operatorname{rbind}(x,y)$	Combine data columnor row-wise.	x <- 1:5; y <- 6:10; cbind(x, y); rbind(x,y)
do.call(function, list)	Iteratively call a function on a list	$my_{list} < -list(x = 1:5, y = 6:10, z = 11:15);$ do.call(cbind, my_list)
merge(x, y, by = 'linking_var')	Join data by a linking variable.	data1 <- data.frame(survey_id = 1:5, wage = rnorm(5, mean = 15, sd = 5)) data2 <- data.frame(survey_id = 5:1, experience = rnorm(5, mean = 5, sd = 3)) data_merge <- merge(data1, data2, by = 'survey_id')
$\begin{array}{c} \text{subset(data, condition);} \\ \text{x[condition]} \end{array}$	Subset data via relational and logic operators.	subset(mtcars, mpg > $30 \& \text{ wt} > 1.7$)
split(data, grouping_variable)	Split data by a grouping variable	split(mtcars, mtcars\$gear)

Chapter 4

String Functions

String functions allow us to combine, pattern-match, and substitute character vectors. These functions are useful for detecting and recoding specific values.

4.1 Concatenate Strings

There are two concatenation functions we can use: paste() and paste0(). The former assumes you want to separate the concatenated elements with a space, whereas the latter will assume no separation.

```
paste('a', 'b')

## [1] "a b"

paste('a', 'b', sep = '-')

## [1] "a-b"

paste0('a', 'b')

## [1] "ab"
```

4.2 Subset Strings

In Excel, we can subset strings with LEFT(), MID(), and RIGHT(). In R, we can subset strings with substr()/substring(), which both act similarly as MID() from Excel.

```
x <- 'Albatross'
substr(x, 1, 4)</pre>
```

```
## [1] "Alba"
substring(x, 5) # Goes to the end by default
## [1] "tross"
```

4.3 Split Strings

We can split strings with the strsplit() function. The output is a list, where each list element is a character vector.

```
x <- c('This is a sentence.',
       'This is another sentence.',
       'This is yet another sentence.')
х
## [1] "This is a sentence."
                                          "This is another sentence."
## [3] "This is yet another sentence."
# Split vector elements by space
my_split <- strsplit(x, split = ' ')</pre>
# Output is a list
my_split
## [[1]]
## [1] "This"
                    "is"
                                 "a"
                                              "sentence."
##
## [[2]]
                                 "another"
## [1] "This"
                    "is"
                                              "sentence."
##
## [[3]]
## [1] "This"
                    "is"
                                 "yet"
                                              "another"
                                                           "sentence."
```

We can use do.call() and c() to combine these list elements into a single vector for a total of 13 elements. The function do.call() iteratively executes a function and c() ("combine") combines elements into a vector.

```
do.call(c, my_split)

## [1] "This"    "is"    "a"    "sentence." "This"    "is"

## [7] "another"    "sentence."    "This"    "is"    "yet"    "another"

## [13] "sentence."
```

4.4 Substitute Strings

We can make character substitutions with gsub().

4.5 Match String Patterns

We can pattern-match strings with grep() and grep1(). The former outputs the position (or value) of a pattern match, while the latter outputs a Boolean value (i.e. TRUE/FALSE).

```
# Cars that start witih "M"
grep('^M', rownames(mtcars), value = TRUE)
    [1] "Mazda RX4"
                        "Mazda RX4 Wag" "Merc 240D"
                                                        "Merc 230"
                                        "Merc 450SE"
    [5] "Merc 280"
                        "Merc 280C"
                                                        "Merc 450SL"
    [9] "Merc 450SLC"
                        "Maserati Bora"
# Which cars start with and do not start with "M"?
grepl('^M', rownames(mtcars))
        TRUE TRUE FALSE FALSE FALSE FALSE TRUE TRUE TRUE TRUE TRUE
## [13] TRUE TRUE FALSE FALSE FALSE FALSE FALSE FALSE FALSE FALSE FALSE FALSE
## [25] FALSE FALSE FALSE FALSE FALSE TRUE FALSE
# Selecting columns that start with "m".
# We set drop = FALSE to maintain a data frame.
head(mtcars[, grep('^m', names(mtcars)), drop = FALSE])
##
                     mpg
## Mazda RX4
                     21.0
## Mazda RX4 Wag
                     21.0
## Datsun 710
                     22.8
## Hornet 4 Drive
                     21.4
## Hornet Sportabout 18.7
## Valiant
                     18.1
```

Check out more regular expressions with RStudio's cheat sheet on strings.

4.6 Summary

Table 4.1: Summary of String Functions

	4.1: Summary of String Fu	
Function	Description	Example
paste(x, y)/paste0(x, y)	Concatenation of x and	paste('a', 'b');
	у.	paste0('a', 'b')
substr(x, start, end)	Subset strings.	substr('Albatross', 1, 4)
strsplit(x, split = ', ')	Split a string by a	x < -c('This is a
	splitting character.	sentence.', 'This is
		another sentence.',
		'This is yet another
		sentence.')
		strsplit(x, split = ', ')
gsub(pattern,	Substitute a portion of	gsub('sentence', 'drink',
replacement, x)	a string vector based on	'This is a sentence.')
	a given pattern.	
grep/grepl(pattern,	Pattern match a string	$\operatorname{grep}(^{\prime}\widehat{M}^{\prime},$
vector)	and output its position	rownames(mtcars),
	OR Boolean (i.e.	value = TRUE
	TRUE/FALSE).	

Chapter 5

Control Flow

Control flow statements allow us to control the flow of our script or data. This functionality is useful for when we want different results depending on specific conditions.

5.1 if and ifelse()

The if statement controls the flow of your R script, branching out to different possibilities if a condition is not met.

```
x <- 2
if (x == 2) {
   'x is 2!'
} else if (x == 3) {
   'x is 3!'
} else {
   'x is not 2 nor 3!'
}</pre>
```

[1] "x is 2!"

The ifelse() function, on the other hand, controls the flow of your vector.

```
x <- c(1:10)
```

5.2 Loops

Loops allow the user to operate on data iteratively, which is useful for reducing repetitive code.

5.2.1 for loop

In a for loop, we iterate over data for each data element in a sequence.

```
# Structure of a for loop
x <- c() # empty vector or list.

# For each data element in some_data...
for (i in seq_along(some_data)) {
   do_something(some_data[, i])
      # The "i" represents the column position in this case.
}</pre>
```

Let's take this example: getting the means for each column in the dataset \mathtt{mtcars} , which is pre-loaded into R.

```
# Getting the means for each column in mtcars.

## Create an empty vector into which we will

## store means.

x <- c()

## For each variable in mtcars...

for (i in seq_along(mtcars)) {

    ### Store the mean of that variable
    ### into x.

    x[i] <- mean(mtcars[, i])
}</pre>
```

[1] 20.090625 6.187500 230.721875 146.687500 3.596563 3.217250

5.2. LOOPS 37

```
## [7] 17.848750 0.437500 0.406250 3.687500 2.812500
```

There is actually a much better way to get the means of all columns in a dataset, which will be discussed in the *Functionals* chapter. In the meantime, the following is a more complex use-case of a for loop.

For more on graphs, see the *Graphing* chapter.

5.2.2 while loop

In contrast to the for loop, the while loop iterates over data until the specified condition breaks (i.e., no longer true).

```
# Set an initial value for the while loop.
x <- 0
# While x is less than 10...
while (x < 10) {
  # Add 1 to it...
  x < -x + 1
  # And then print it to the console.
  print(x)
## [1] 1
## [1] 2
## [1] 3
## [1] 4
## [1] 5
## [1] 6
## [1] 7
## [1] 8
## [1] 9
## [1] 10
```

5.3 Summary

5.3. SUMMARY 39

Table 5.1: Control Flow Statements

Statement.or.Function	Description	Example
if (condition) {output}	Control the flow of the	if $(x == 2) \{ 'x \text{ is } 2!' \}$
	R script.	else $\{$ 'x is not $2!$ ' $\}$
ifelse(test, yes, no)	Control the flow of a	ifelse(1:10 $\%\%$ 2 == 0,
	vector.	'even', 'odd')
for (statement)	Iterate over each data	x <- c();
$\{ output \}$	element.	for (i in
		$seq_along(mtcars))$ {
		$x[i] \leftarrow mean(mtcars[, i])$
		};
		X
while (condition)	Iterate over data until a	x < 0;
$\{\text{output}\}$	condition breaks.	while $(x < 10)$ {
		x < -x + 1
		print(x)
		}

Chapter 6

Descriptive Statistics

There are various functions for descriptive statistics in R. The below subsections show a selected sample.

6.1 Centrality and Spread

Like in Microsoft Excel, we can cast centrality and spread functions on a variable.

```
k <- c(1, 5, 7, 9)
mean(k)

## [1] 5.5

# Use the $ operator for columns in a dataset
mean(mtcars$mpg)

## [1] 20.09062
sd(mtcars$mpg)

## [1] 6.026948</pre>
```

If you want to use multiple functions on a single variable, the with() function can be useful, as it lets you define the local environment to be the desired dataset so that you do not have to use the \$ operator repeatedly.

```
with(mtcars, c(mean = mean(mpg), median = median(mpg), sd = sd(mpg)))
## mean median sd
## 20.090625 19.200000 6.026948
```

6.2 Minimum and Maximum

To compute the minimum and maximum of a variable, we can use the min() and max() functions respectively.

```
x <- 1:10 # 1 through 10.
min(x)
## [1] 1
max(x)
## [1] 10</pre>
```

6.3 Data Dimensions

To know the dimensions of an object in R, we can use nrow()/NROW for the number of rows; ncol()/NCOL() for the number of columns; and dim() for number of both rows and columns simultaneously.

```
NROW(mtcars)
## [1] 32
NCOL(mtcars)
## [1] 11
dim(mtcars)
## [1] 32 11
```

6.4 Data Summary

We can cast summary() on an object to capture summary information on an object. This function is useful following str(), as you can get a sense of what your dataset is like.

```
# Preview the dataset
str(iris)

## 'data.frame': 150 obs. of 5 variables:
## $ Sepal.Length: num 5.1 4.9 4.7 4.6 5 5.4 4.6 5 4.4 4.9 ...
## $ Sepal.Width : num 3.5 3 3.2 3.1 3.6 3.9 3.4 3.4 2.9 3.1 ...
## $ Petal.Length: num 1.4 1.4 1.3 1.5 1.4 1.7 1.4 1.5 1.4 1.5 ...
## $ Petal.Width : num 0.2 0.2 0.2 0.2 0.2 0.4 0.3 0.2 0.2 0.1 ...
## $ Species : Factor w/ 3 levels "setosa", "versicolor", ..: 1 1 1 1 1 1 1 1 1 1 1 1
```

```
# Summarize the dataset.
summary(iris)
##
     Sepal.Length
                      Sepal.Width
                                       Petal.Length
                                                        Petal.Width

##
    Max.
           :7.900
                     Max.
                                      Max.
                                             :6.900
                                                       {\tt Max.}
##
          Species
##
               :50
    setosa
    versicolor:50
##
##
    virginica:50
##
##
##
```

Note that because **Species** is a factor variable, we obtain counts by category for that column instead of quantiles and means like the others.

6.5 Frequency Tables

To get counts by groups, we can use the table() function, while using prop.table() on a table() computation produces proportions. The input of table() can be one to two columns and the output is a table class.

6.5.1 Single-variable Case

```
my_table <- table(iris$Species)

my_table

##

## setosa versicolor virginica
## 50 50 50

prop.table(my_table)

##

## setosa versicolor virginica
## 0.3333333 0.3333333 0.3333333</pre>
```

6.5.2 Multi-variable Case

```
my_table2 <- with(mtcars, table(am, gear))</pre>
my_table2
      gear
##
## am
        3 4
              5
     0 15
          4
##
     1 0 8
              5
my_table3 <- with(mtcars, table(am, gear, cyl))</pre>
my_table3
## , cyl = 4
##
##
      gear
        3
##
           4 5
   am
           2
##
     0
        1
              0
##
     1
        0
           6 2
##
##
   , , cyl = 6
##
##
      gear
##
        3
          4 5
        2
          2 0
##
     0
##
        0
           2 1
##
##
   , cyl = 8
##
##
      gear
##
        3
           4 5
     0 12
##
          0 0
     1
        0
           0
              2
##
```

6.5.3 Converting to a Data Frame

If we apply the as.data.frame() function to an object of a table class, the output would be structured in a way such that we have a column (or columns) containing the group(s) and a column for the frequency. The structure is useful, as it is in a format that is acceptable for CSV output, for example.

```
freq <- table(iris$Species)
prop <- prop.table(freq)
as.data.frame(freq)</pre>
```

6.6. SUMMARY 45

```
##
           Var1 Freq
## 1
         setosa
## 2 versicolor
                   50
## 3 virginica
as.data.frame(prop)
##
           Var1
                      Freq
## 1
         setosa 0.3333333
## 2 versicolor 0.3333333
## 3 virginica 0.3333333
my_table_df <- merge(as.data.frame(freq), as.data.frame(prop), by = 'Var1')</pre>
names(my_table_df) <- c('Species', 'Frequency', 'Percent')</pre>
my_table_df
##
        Species Frequency Percent
## 1
       setosa 50 0.3333333
## 2 versicolor 50 0.3333333
## 3 virginica 50 0.33333333
write.csv(my_table_df, 'my_example_table.csv')
```

6.6 Summary

Table 6.1: Summary of Descriptive Statistics Functions

Function	Description	Example
mean(x)	Computes the mean.	$mean(mtcars \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \$
sd(x)	Computes the standard	$sd(mtcars \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \$
1: ()	deviation.	
median(x)	Computes the median.	median(mtcars\\$mpg)
$\min(x)$	Computes the minimum.	$\min(\text{mtcars} \setminus \text{$mpg})$
max(x)	Computes the	$\max(\text{mtcars} \setminus \text{\$mpg})$
	maximum.	
nrow(x)/NROW(x)	Computes the number	nrow(mtcars);
	of rows.	NROW(mtcars)
ncol(x)/NCOL(x)	Computes the number	ncol(mtcars);
	of columns.	NCOL(mtcars)
dim(x)	Computes the number	dim(mtcars)
	of rows and columns.	
length(x)	Computes the number	$length(mtcars\space)$
	of elements in a data	
	object.	
summary(x)	Summarizes a dataset.	summary(mtcars)
table(x)	Generates a frequency	$table(mtcars \S ear);$
	table for one or more	with(mtcars, table(gear,
	variables.	am))
prop.table(table)	Generates a	prop.table(table(mtcars\\$gea
, ,	proportions table.	, , , , ,

Chapter 7

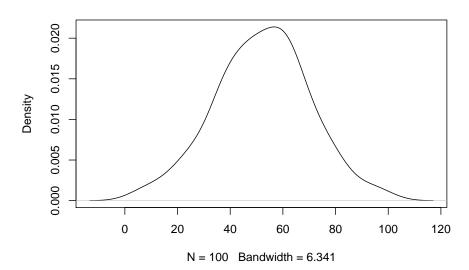

Probability Functions

This chapter will primarily focus on the normal distribution functions in R.

7.1 Generating Random Numbers

To calculate random numbers in R based on a normal distribution, we can use the rnorm() function. By default, the mean and sd respectively are 0 and 1; but we can change these parameters as necessary.

100 Random Numbers

See more on plots in the *Graphing* chapter.

7.2 Sampling

Duster 360

Mazda RX4

We can take a random sampling of a vector with sample().

14.3

21.0

```
set.seed(1) # Remember our random values.
# 10 random numbers from
    a vector of 100 values.
sample(1:100, size = 10, replace = TRUE)
   [1] 68 39 1 34 87 43 14 82 59 51
For a dataset, we can do the following:
set.seed(1) # Remember our random values.
# Random 5 rows
mtcars[sample(1:NROW(mtcars), 5), ]
##
                     mpg cyl disp hp drat
                                              wt qsec vs am gear carb
## Pontiac Firebird 19.2
                          8 400 175 3.08 3.845 17.05
## Hornet 4 Drive
                    21.4
                           6
                              258 110 3.08 3.215 19.44
                                                         1
                                                                 3
```

8 360 245 3.21 3.570 15.84

7.4 Summary

Table 7.1: Summary of Probability Distributions

Function	Description	Example
rnorm(x)	x random numbers	rnorm(10)
	based on a normal	
	distribution.	
sample(x, size)	Sample a vector with a	sample(1:100, size =
	specified size.	10)
Other probability	See '?rnorm', '?rchisq',	
functions.	and '?rpois'	

Chapter 8

Function Writing

Writing functions allows us to condense a process into a single function.

8.1 Univariate Case

If we wanted to index a variable by its mean, we could simply type x/mean(x), where x is our vector. However, what if there were a function called index() that makes this process more clear? There is not one inherently in R, but we are able to create it:

```
index <- function(x) { # the formals/arguments</pre>
  x/mean(x) # The body
}
index(mtcars$mpg)
    [1] 1.0452636 1.0452636 1.1348577 1.0651734 0.9307824 0.9009177 0.7117748
    [8] 1.2144968 1.1348577 0.9556696 0.8859854 0.8163011 0.8610981 0.7565718
## [15] 0.5176544 0.5176544 0.7316846 1.6126925 1.5131436 1.6873542 1.0701509
## [22] 0.7715041 0.7565718 0.6620003 0.9556696 1.3588427 1.2941359 1.5131436
## [29] 0.7864365 0.9805569 0.7466169 1.0651734
We can cast this new function over all columns in mtcars with sapply().
# Get only a few rows.
head(sapply(mtcars, index))
##
                                                       drat
                         cyl
                                  disp
                                              hp
                                                                            qsec
              mpg
```

 $^{^{1}\}mathrm{See}$ the Functionals chapter for more on sapply() and its bretheren.

```

```

8.2 Multivariate Case

In the univariate case, we indexed a vector by its mean. What if we wanted to use the median instead? We would simply need to replace mean with median. Alternatively, we can add an additional input into our function that specifies what aggregation function to use in the indexing.

```
index2 <- function(x, f) {
   x/f(x)
}</pre>
```

Now we can use any function in the f input.

```
head(index2(mtcars$mpg, mean)) # show only a few elements

## [1] 1.0452636 1.0452636 1.1348577 1.0651734 0.9307824 0.9009177
head(index2(mtcars$mpg, median)) # show only a few elements

## [1] 1.0937500 1.0937500 1.1875000 1.1145833 0.9739583 0.9427083
head(index2(mtcars$mpg, max)) # show only a few elements

## [1] 0.6194690 0.6194690 0.6725664 0.6312684 0.5516224 0.5339233
```

Our index2 function is actually special in that it is not only a multivariate function but a *functional*, which is a function that takes another function as an input—see the *Functionals* chapter for more details.

8.3 Summary

8.3. SUMMARY 53

Table 8.1: Summary of Function Writing

Function	Description	Example
function(x)	Write a function, which consists of arguments and the body.	$ \begin{array}{l} index <- \ function(x) \\ x/mean(x) \end{array} $

Chapter 9

Functionals

Functionals are functions that take a function as an input and output a value. They are useful for casting a function over all columns in a dataset or elements in a list

This chapter will demonstrate a select handful of functionals—see <code>?lapply</code> for more information.

9.1 lapply()

The lapply() function ("list apply") casts a function over a dataset and outputs a list.

```
lapply(mtcars, mean)
```

```
## $mpg
## [1] 20.09062
##
## $cyl
## [1] 6.1875
##
## $disp
## [1] 230.7219
##
## $hp
## [1] 146.6875
##
## $drat
## [1] 3.596563
##
## $wt
```

```
## [1] 3.21725
##
## $qsec
## [1] 17.84875
##
## $vs
## [1] 0.4375
##
## $am
## [1] 0.40625
##
## $gear
## [1] 3.6875
##
## $carb
## [1] 2.8125
```

9.2 sapply()

The sapply() function ("simplified apply") casts a function over a dataset and outputs a matrix (or list, depending on the function).

```
sapply(mtcars, mean)
##
                                 disp
                                                        drat
                                                                      wt
          mpg
                      cyl
                                               hp
                                                                                qsec
                                                    3.596563
##
    20.090625
                 6.187500 230.721875 146.687500
                                                                3.217250
                                                                          17.848750
##
           vs
                       am
                                 gear
                                             carb
##
     0.437500
                 0.406250
                             3.687500
                                        2.812500
```

9.3 apply()

The apply() function can cast a function over a dataset row-wise or column-wise, returning a matrix.

```
# Row-wise means.
# show only a few with head().
head(apply(mtcars, 1, mean))
                          Mazda RX4 Wag
##
           Mazda RX4
                                                Datsun 710
                                                               Hornet 4 Drive
##
            29.90727
                               29.98136
                                                  23.59818
                                                                     38.73955
## Hornet Sportabout
                                Valiant
            53.66455
                               35.04909
# Column-wise means.
apply(mtcars, 2, mean)
##
          mpg
                      cyl
                                disp
                                              hp
                                                        drat
                                                                     wt
                                                                               qsec
```

9.4. VAPPLY() 57

```
##
    20.090625
                 6.187500 230.721875 146.687500
                                                    3.596563
                                                                3.217250
                                                                          17.848750
##
           VS
                                 gear
                                             carb
                       am
##
     0.437500
                 0.406250
                             3.687500
                                         2.812500
```

9.4 vapply()

The vapply() function ("vectorized apply") works similarly as sapply(); however, there is a type-checking component to it. In other words, one can set whether the output should be numeric or character, for example, beforehand. If the output does not match the set type, an error will occur. This function is useful for type-checking your results (i.e., making sure the output matches your expectations).

```
# Mean of all mtcars columns
# Type-check whether it is a numeric vector.
vapply(mtcars, mean, numeric(1))
##
          mpg
                     cyl
                                disp
                                             hp
                                                       drat
                                                                    wt
                                                                              qsec
                6.187500 230.721875 146.687500
    20.090625
                                                   3.596563
                                                              3.217250
                                                                        17.848750
##
##
           ٧s
                       am
                                gear
                                           carb
##
     0.437500
                0.406250
                            3.687500
                                       2.812500
# Mean of all mtcars columns
# Type-check whether it is a character vector.
vapply(mtcars, mean, character(1))
## Error in vapply(mtcars, mean, character(1)): values must be type 'character',
## but FUN(X[[1]]) result is type 'double'
```

$9.5 \quad \text{mapply()/Map()}$

The functions mapply() and Map() allow us to compute a function iteratively over one or more data inputs.

9.5.1 Univariate Case

\$mpg

In the univariate case, mapply()/Map() work similarly as sapply()/lapply().

```
mapply(mean, mtcars)
##
                      cyl
                                 disp
                                               hp
                                                        drat
                                                                                qsec
          mpg
##
    20.090625
                 6.187500 230.721875 146.687500
                                                    3.596563
                                                                3.217250
                                                                          17.848750
##
           ٧s
                       am
                                 gear
                                             carb
     0.437500
                 0.406250
                            3.687500
                                        2.812500
head(Map(mean, mtcars)) # Just show a few.
```

```
## [1] 20.09062
##
## $cyl
## [1] 6.1875
##
## $disp
## [1] 230.7219
##
## $hp
## [1] 146.6875
##
## $drat
## [1] 3.596563
##
## $wt
## [1] 3.21725
```

9.5.2 Multivariate Case

In the multivariate case, we can have multiple data inputs.

```
# Row bind mpg and wt from mtcars.
# Output = matrix
# Show only a few columns.
mapply(rbind, mtcars$mpg, mtcars$wt)[, 1:5]
         [,1]
              [,2] [,3]
                             [,4] [,5]
## [1,] 21.00 21.000 22.80 21.400 18.70
## [2,] 2.62 2.875 2.32 3.215 3.44
# Row bind mpg and wt from mtcars.
# Output = list.
# Show only a few rows.
head(Map(rbind, mtcars$mpg, mtcars$wt))
## [[1]]
##
        [,1]
## [1,] 21.00
## [2,] 2.62
##
## [[2]]
##
          [,1]
## [1,] 21.000
## [2,] 2.875
##
## [[3]]
##
         [,1]
```

9.6. RAPPLY() 59

```
## [1,] 22.80
##
  [2,] 2.32
##
  [[4]]
##
          [,1]
##
## [1,] 21.400
## [2,] 3.215
##
## [[5]]
##
         [,1]
## [1,] 18.70
## [2,] 3.44
##
## [[6]]
##
         [,1]
## [1,] 18.10
## [2,] 3.46
```

9.6 rapply()

The rapply() function allows one to iterate over a list of datasets recursively. In other words, it allows us to compute the means for all datasets in a list simultaneously, for example.

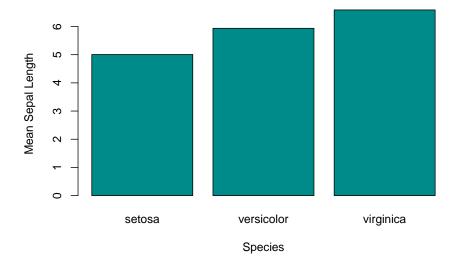

```
##
                           cyl
                                        disp
                                                        hp
                                                                    drat
                                                                                    wt
             mpg
      20.090625
##
                     6.187500
                                 230.721875
                                                146.687500
                                                                3.596563
                                                                              3.217250
##
                                                                                  Wind
                            VS
                                          am
                                                                    carb
            qsec
                                                      gear
##
      17.848750
                     0.437500
                                    0.406250
                                                                2.812500
                                                                              9.957516
                                                  3.687500
## Sepal.Length
                  Sepal.Width Petal.Length
                                              Petal.Width
##
       5.843333
                     3.057333
                                    3.758000
                                                  1.199333
```

9.7 tapply()

The function tapply() makes group-wise computations, outputting a vector as a result. The output being a vector can be useful when passing to other functions,

such as barplot(). As such, you may want to use tapply() when (1) you want your grouped-computation output to be a vector of values and (2) you want to interact the output values with another function.

```
# Let's use iris, a pre-loaded dataset in R.
means <- with(iris, tapply(Sepal.Length, Species, mean))
means
## setosa versicolor virginica
## 5.006 5.936 6.588
barplot(means, col = 'cyan4', ylab = 'Mean Sepal Length', xlab = 'Species')</pre>
```

9.8 aggregate()

Similar to tapply(), the function aggregate() allows you to make groupwise calculations; however, the output is a data frame rather than a vector. Additionally, you can input multiple independent variables (i.e. variables on the right-hand side of the formula syntax, $y \sim x$). This function may be preferred over tapply() when (1) you want multiple grouping variables and (2) you want your output to be in a 2-dimensional format.

```
# Get the mean MPG by gear and am.
my_agg <- aggregate(mpg ~ gear + am, mtcars, mean)</pre>
```

9.9. SUMMARY 61

my_agg

```
## 1 gear am mpg
## 1 3 0 16.10667
## 2 4 0 21.05000
## 3 4 1 26.27500
## 4 5 1 21.38000
```

9.9 Summary

Table 9.1: Summary of Functionals

Function	Description	Example
lapply(X, FUN)	Compute a function over data and output a	lapply(mtcars, mean)
	list.	
sapply(X, FUN)	Compute a function	sapply(mtcars, mean)
	over data and output a	
	matrix (sometimes a	
	list, depending on the	
	function being passed).	
apply(X, MARGIN,	Compute a function	apply(mtcars, 1, mean);
FUN)	row-wise or	apply(mtcars, 2, mean)
	column-wise.

Chapter 10

Graphing

The following subsections show examples of how to create certain types of graphs.

10.1 Histograms

All we need to make a histogram is to pass a vector into the hist() function.

```
hist(mtcars$mpg,
    col = 'cyan4',
    xlab = 'MPG',
    ylab = 'Frequency',
    main = 'MPG Distribution')
```

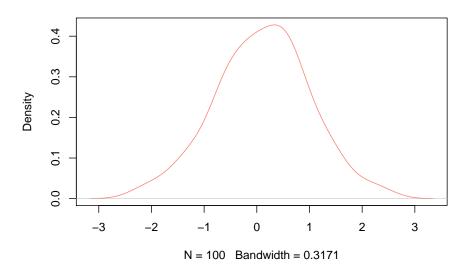

MPG Distribution Leading of the state of th

```
set.seed(1) # Remember our random numbers.

x <- density(rnorm(100))

plot(x,
    main = '100 Random Numbers',
    col = 'salmon')</pre>
```

100 Random Numbers

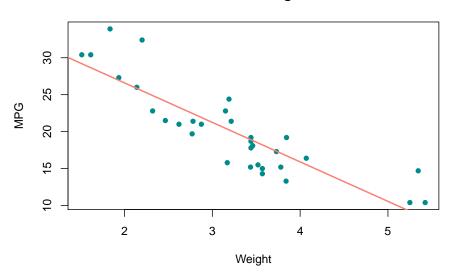

10.3 Scatter Plots

To make a scatter plot, we make use of the plot(formula) function, where formula input is of the syntax $y \sim x$ (y relates to the y-axis and relates to the x-axis).

10.3.1 Simple Scatter Plot

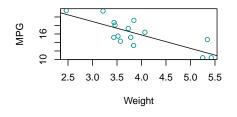

10.3.2 Multiple Scatter Plots

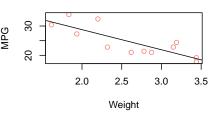

For a more complex example, let's make multiple scatter plots via a for loop.

```
# Set up a 2x2 canvas
par(mfrow = c(2,2))
# Set parameters
unique_gears <- sort(unique(mtcars$gear))</pre>
mycolors <- c('cyan4', 'salmon','forestgreen', 'purple')</pre>
# Begin plot loop
for (i in seq_along(unique_gears)) {
  # Subset by number of gears
  ss <- subset(mtcars, gear == unique_gears[i])</pre>
  # Plot a scatter points
  with(ss,
       plot(mpg ~ wt,
            col = mycolors[i],
            ylab = 'MPG',
            xlab = 'Weight',
            main = pasteO('MPG vs. Weight (No. of Gears = ',
```

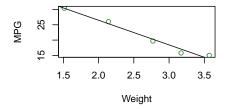

MPG vs. Weight (No. of Gears = 3)

MPG vs. Weight (No. of Gears = 4)

MPG vs. Weight (No. of Gears = 5)

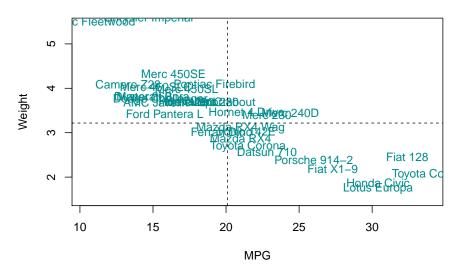

Notice how "purple" isn't used in graphs, as there are only three sub-graphs to plot

10.3.3 Text Plot

To make a text plot, we just turn off the points in the plot() function via type = 'n' and then use the text() function to label them on the graph.

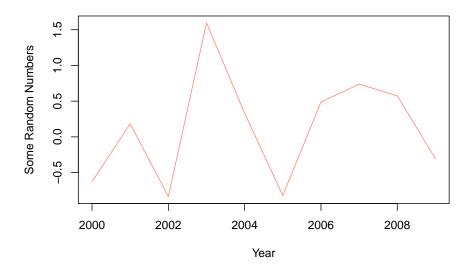

Weight vs. MPG

10.4 Line Plots

Making a line plot is similar to making a scatter plot except that we set type = '1' as an additional input.

10.5. BOX PLOTS

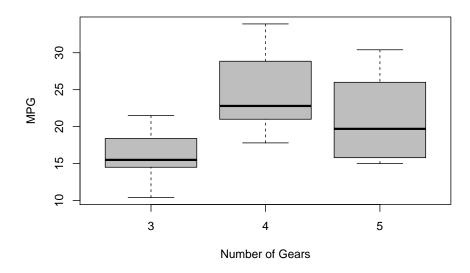

10.5 Box Plots

Constructing a box plot with the boxplot() function is similar to making a scatter plot with plot(): we pass a formula of vectors into it.

```
with(mtcars,
    boxplot(mpg ~ gear,
        ylab = 'MPG',
        xlab = 'Number of Gears',
        main = 'Box Plot of MPG vs. Number of Gears',
        col = 'grey'))
```

10.6 Bar Plots

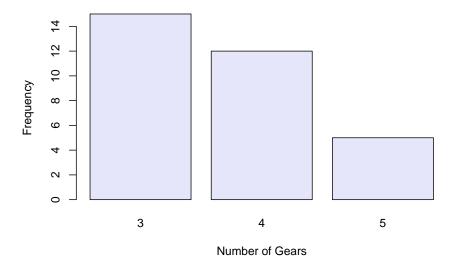

For a bar plot, we pass a vector (usually one of counts) or aggregation to barplot().

10.6.1 Frequency Chart

For a frequency chart, we have to calculate a table of frequencies with the table() function before passing it to barplot().

10.6. BAR PLOTS

Frequencies by Number of Gears

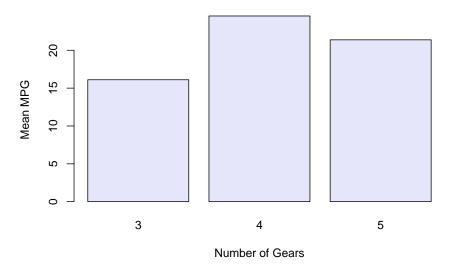

10.6.2 Grouped Mean Comparisons

For grouped mean comparisons, we have to aggregate data with aggregate() (see the Functionals chapter for more details) before passing it to barplot().

```
my_agg <- aggregate(mpg ~ gear, mtcars, mean)
with(my_agg,
    barplot(mpg ~ gear,
        beside = TRUE, # Set to FALSE to stack bars.
    ylab = 'Mean MPG',
    xlab = 'Number of Gears',
    main = 'Mean MPG by Number of Gears',
    col = 'lavender'))</pre>
```

Mean MPG by Number of Gears

10.7 Summary

Table 10.1: Summary of Graphing Functions

Function	Description	Example
hist(x)	Histogram	$hist(mtcars \S pg)$
plot(density(x))	Density plot	plot(density(rnorm(100)))
$plot(y \sim x)$	Scatter plot	with(mtcars, plot(mpg
		~ wt))
$plot(y \sim x, type = 'l')$	Line plot	with(Orange,
		$plot(circumference \sim$
		age, type = 'l'))
$boxplot(y \sim x)$	Box plot	with(mtcars,
		$boxplot(mpg \sim wt))$
barplot(x)	Bar plot	$barplot(table(mtcars \ \$gear))$

Chapter 11

Hypothesis Testing

In this chapter, we will cover how to conduct a t-test of means and chi-square test of frequencies.

11.1 t-test

To conduct a t-test, we use the t.test() function. What we input into this function depends on whether we want to compute a one-sample or two-sample test.

11.1.1 One-sample t-test

To conduct a 1-sample t-test, we pass a vector and a mu value into the t.test() function. The mu value is the number against which we will compare the vector's mean to determine whether there is a statistically significant difference.

```
# Testing whether the mean MPG is statistically equal to 17.
t.test(mtcars$mpg, mu = 17)
```

```
##
## One Sample t-test
##
## data: mtcars$mpg
## t = 2.9008, df = 31, p-value = 0.006788
## alternative hypothesis: true mean is not equal to 17
## 95 percent confidence interval:
## 17.91768 22.26357
## sample estimates:
## mean of x
## 20.09062
```

11.1.2 Two-sample t-test

To conduct a two-sample t-test, we use the formula syntax of $y \sim x$, where y is our continuous dependent variable and x is our categorical independent variable. Then, we pass this formula into t.test().

```
# Compare mean MPG by transmission type
with(mtcars, t.test(mpg ~ am))
##
##
   Welch Two Sample t-test
##
## data: mpg by am
## t = -3.7671, df = 18.332, p-value = 0.001374
## alternative hypothesis: true difference in means is not equal to 0
## 95 percent confidence interval:
## -11.280194 -3.209684
## sample estimates:
## mean in group 0 mean in group 1
##
          17.14737
                          24.39231
```

11.2 Chi-square test

To conduct a Chi-square test, we pass a two-way table into the chisq.test() function

```
mytable <- with(mtcars, table(gear, am))</pre>
mytable
##
       am
## gear
         0
            1
      3 15
##
      4
         4
            8
##
      5
         0
            5
chisq.test(mytable)
## Warning in chisq.test(mytable): Chi-squared approximation may be incorrect
##
##
    Pearson's Chi-squared test
##
## data: mytable
## X-squared = 20.945, df = 2, p-value = 2.831e-05
```

11.3 Summary

11.3. SUMMARY 75

Table 11.1: Summary of Hypothesis Testing

Function	Description	Example
t.test(x, mu)	Test of mean against mu.	t.test(mtcars\$mpg, mu = 17)
$t.test(y \sim x)$	Test of group means.	with(mtcars, t.test(mpg
chisq.test(table)	Test of two-way frequencies.	\sim am)) with(mtcars, chisq.test(table(gear, am)))

Chapter 12

Linear Modeling

In this chapter, we will examine Pearson correlations, ANOVA, Ordinary Least Squares, and logistic regression.

12.1 Pearson Correlations

To estimate a Pearson correlation for all variables in a dataset, we pass a matrix or data frame into the cor() function.

```
# Pearson correlation coefficient matrix
cor(mtcars)
```

```

To perform a correlation test in which we produce a p-value, we pass two vectors into the cor.test() function.

```
# Pearson correlation coefficient test
with(mtcars, cor.test(mpg, wt))
```

```
##
## Pearson's product-moment correlation
##
## data: mpg and wt
## t = -9.559, df = 30, p-value = 1.294e-10
## alternative hypothesis: true correlation is not equal to 0
## 95 percent confidence interval:
## -0.9338264 -0.7440872
## sample estimates:
## cor
## -0.8676594
```

To get p-values from a correlation matrix for all variables, we will use the Hmisc package. We install it with install.packages() and then load it with library(). We use the library's rcorr() function to calculate the correlation and p-values matrices.

```
install.packages('Hmisc') # Install first.
```

```
# Load the library into the environment.
library(Hmisc)

my_corr <- rcorr(as.matrix(mtcars), type = 'pearson')

# Pearson correlation coefficients
my_corr$r</pre>
```

```

12.2 ANOVA

To conduct ANOVA, we pass a formula and dataset into the aov() function. Note that the independent variables must be factor variables, so we must use the factor() function on our independent variables if they are not already factors.

```
my_anova <- aov(mpg ~ factor(gear) + factor(am), mtcars)</pre>
my_anova
## Call:
##
      aov(formula = mpg ~ factor(gear) + factor(am), data = mtcars)

```

12.3.1 Residual diagnostics with OLS

To analyze the performance of our models with respect to our residuals, we can calculate the predicted values with predict() and residuals with resid(). We can then plot them to see whether the residuals behave in a homoskedastic manner.

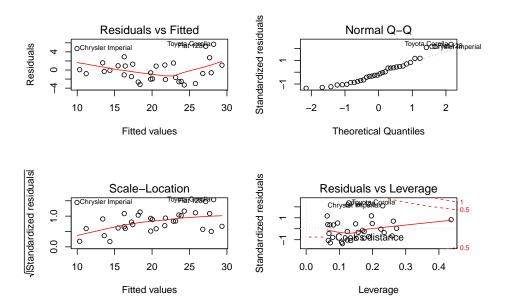

```
fit <- predict(my_ols)
res <- resid(my_ols)

plot(res ~ fit)
abline(lm(res ~ fit), lty = 2)</pre>
```

Alternatively, we can directly plot our model. Make sure to set a 2-by-2 canvas beforehand so that all the plots from plot() will generate simultaneously.

```
par(mfrow = c(2,2)) # Set 2x2 canvas
plot(my_ols)
```

12.4 Logistic Regression

Estimating a logistic regression is similar to estimating a model with OLS; however, we add an additional input in which we set the distribution family—in this case, it is the binomial one.

```
my_logit <- glm(am ~ mpg + wt + gear,</pre>
                mtcars,
                family = binomial(link = 'logit'))
## Warning: glm.fit: algorithm did not converge
## Warning: glm.fit: fitted probabilities numerically 0 or 1 occurred
my_logit
##
        glm(formula = am ~ mpg + wt + gear, family = binomial(link = "logit"),
##
       data = mtcars)
##
## Coefficients:
##
   (Intercept)
                         mpg
                                       wt
                                                   gear
##

Chapter 13

Recommended R Libraries

The following is a list of recommended R libraries to install—they can be helpful for data management, graphing, and formatting.

13.1 tidyverse

The tidyverse package is a metapackage consisting of other libraries. The most useful ones for a beginner, I believe, are ggplot2, dplyr, tidyr, and purrr.

For more information, see the tidyverse website.

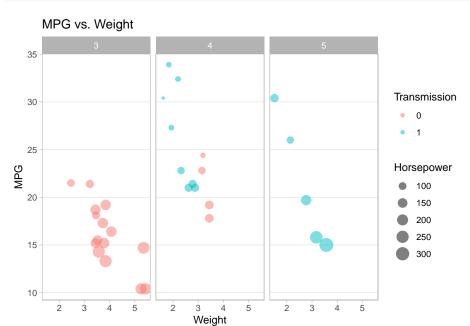

```
install.packages('tidyverse')
library(tidyverse)
```

13.1.1 ggplot2

The library ggplot2 offers visualization tools with a modern aesthetic. The following is an example of a small-multiples¹ scatter plot. For more information, see the ggplot2 website.

¹https://en.wikipedia.org/wiki/Small_multiple

```
theme_light() +
theme(panel.grid.minor = element_blank(),
    panel.grid.major.x = element_blank())
```

13.1.2 dplyr

3

5

The dplyr library provides aggregation tools for data management. The following is an example of calculating the mean and median MPG by gear.

For more information, see the dplyr website.

21.4

```
my_agg <- mtcars %>%
  select(mpg, gear) %>%
  group_by(gear) %>%
  summarise(mean_mpg = mean(mpg),
            median_mpg = median(mpg))
my_agg
## # A tibble: 3 x 3
      gear mean_mpg median_mpg
##
     <dbl>
              <dbl>
                         <dbl>
## 1
         3
               16.1
                          15.5
## 2
         4
               24.5
                          22.8
```

19.7

13.1. TIDYVERSE 89

13.1.3 tidyr

The tidyr library provides pivoting tools to reshape your dataset. The following are examples of how to reformat an aggregation from dplyr's functions.

For more information, see the tidyr website.

```
# Aggregation
my_agg <- mtcars %>%
 select(mpg, gear, am) %>%
  group_by(gear, am) %>%
  summarise(mean_mpg = mean(mpg))
# Pivot wide
my_agg2 <- my_agg %>%
 pivot_wider(id_cols
                         = gear, # rows
             names_from = am, # columns
             values_from = mean_mpg) # values
my_agg2
## # A tibble: 3 x 3
## # Groups: gear [3]
            `0` `1`
##
      gear
##
     <dbl> <dbl> <dbl>
## 1
        3 16.1 NA
        4 21.0 26.3
## 2
## 3
        5 NA
                 21.4
# Pivot long
my_agg2 %>%
 pivot_longer(2:3,
              names_to = 'am',
              values_to = 'mpg',
              values_drop_na = TRUE) # drop NA values
## # A tibble: 4 x 3
## # Groups:
              gear [3]
##
      gear am
                  mpg
##
     <dbl> <chr> <dbl>
## 1
        3 0
                 16.1
## 2
        4 0
                 21.0
## 3
        4 1
                26.3
## 4
        5 1
                 21.4
```

13.1.4 purrr

The purrr library offers functionals similar to the *apply() functions (the former's map() operates similarly as the latter's lapply()); however, the former contains functions that maintain type consistency. For example, there is a function called map_dbl() that throws an error if the output is not a double vector (i.e., a numeric vector), which is useful when you want to catch your program's errors.

The following are some examples from purrr. For more information on how to use these and other functions within the library, see the purrr website.

```
map(mtcars, mean) # == lapply(mtcars, mean)
```

```
## $mpg
## [1] 20.09062
##
## $cyl
## [1] 6.1875
##
## $disp
## [1] 230.7219
##
## $hp
## [1] 146.6875
##
## $drat
## [1] 3.596563
##
## $wt
## [1] 3.21725
##
## $qsec
## [1] 17.84875
##
## $vs
## [1] 0.4375
##
## $am
## [1] 0.40625
##
## $gear
## [1] 3.6875
##
## $carb
## [1] 2.8125
```

13.2. KNITR 91

```
map_dbl(mtcars, mean) # == sapply(mtcars, mean)
##
                                                                                                                                                                                                                                                                                            drat
                                                                                                                                                                                                                                                                                                                                                                                                                  qsec
                                                                                                                 cyl
                                                                                                                                                                      disp

```

13.2 knitr

The knitr library is an "engine for dynamic report generation," which allows for better formatted tables and documentation capabilities when using R Markdown.² The following example demonstrates kable() to format a table.

	U	1
3	15	0
4	4	8
5	0	5

13.3 stargazer

The stargazer library allows one to format a regression model to be closer to journal-quality guidelines.

For more information, see its documentation on CRAN.

```
install.packages('stargazer')
library(stargazer)
##
## Please cite as:
```

²https://yihui.org/knitr/

```
## Hlavac, Marek (2018). stargazer: Well-Formatted Regression and Summary Statistics
## R package version 5.2.2. https://CRAN.R-project.org/package=stargazer
my_ols <- lm(mpg ~ wt + hp + disp + gear + am, mtcars)</pre>
```

If you are using RGui or R Studio and not R Markdown, I recommend to set type = 'text' so that only textual output will be produced instead of LaTeX or HTML code.

```
# If NOT using R Markdown...
stargazer(my_ols, type = 'text')
```

```
##
##
                  Dependent variable:
##
                       mpg
## -----
                     -3.113**
## wt

## -----
## Observations
                       32
## R2
                       0.842
## Adjusted R2
                      0.812
## Residual Std. Error 2.616 (df = 26)
               27.709*** (df = 5; 26)
## F Statistic
## Note:
               *p<0.1; **p<0.05; ***p<0.01
```

If you happen to use R Markdown, then set type = 'html' for HTML documents and omit type for PDF documents.

13.4. SUMMARY 93

For more on R Markdown, see the R Markdown book by Yihui Xie, J. J. Allaire, and Garrett Grolemund.

```
# If using RMarkdown...
# stargazer(my_ols, type = 'html') # for html documents.
stargazer(my_ols) # for PDF documents.
```

% Table created by stargazer v.5.2.2 by Marek Hlavac, Harvard University. E-mail: hlavac at fas.harvard.edu % Date and time: Tue, May 26, 2020 - 1:33:43 PM

13.4 Summary

Table 13.2: Summary of Recommended Libraries

Library	Function	Description	Example
ggplot2	$\begin{array}{l} {\rm ggplot(data)} + \\ {\rm aes(y,x,\ldots)} + \\ {\rm geom_point()} \end{array}$	Scatter plot with ggplot2.	ggplot(mtcars) + aes(y = mpg, x = wt, col = factor(am), size = hp) + geom_point(alpha = 0.5)
dplyr	select(), group_by(), summarise()	Select, group by, and summarise data.	mtcars %>% select(mpg, gear) %>% group_by(gear) %>% sum- marise(mean_mpg = mean(mpg), median_mpg = median(mpg))
tidyr	pivot_wider(), pivot_longer()	Pivot data long or wide.	my_agg <- mtcars %>% select(mpg, gear, am) %>% group_by(gear, am) %>% sum- marise(mean_mpg = mean(mpg)) my_agg2 <- my_agg %>% pivot_wider(id_col = gear, names_from = am, values_from = mean_mpg)
purrr	map(.x, .f)	Apply a function over a data's elements iteratively.	map(mtcars, mean)
knitr	kable(x)	Format a table.	my_table <- with(mtcars, table(gear, am)) kable(my_table)
stargazer	stargazer(x)	Format a regression.	my_ols <- lm(mpg ~ wt + hp + disp + gear + am, mtcars) stargazer(my_ols, type = 'text')

Chapter 14

Conclusion

I hope that these chapters were helpful in teaching you the concepts and syntax structure of R functions. This book is the first time I am writing something akin to a textbook: most of my writing have been academic papers, documentation for my packages, and blog posts, so I hope you have learned at least as much on R as I have on writing this book!

For further reading, I recommend reviewing the *References* and *Resources* sections, as they provide packages, data, and a book for practicing with and learning about R.

Thank you for reading!

Resources

1. UNdata (United Nations' statistical database)

UNdata provides international statistics hosted by the United Nations Statistics Division. It provides general regional profiles that summarize basic demographic, economic, and health data of countries, as well as time-series tables for historical analyses. Highly recommended for social scientists, public policy analysts, and other similar professions.

2. Institute for Digital Research and Education (idre), University of California at Los Angeles

The Institute has tutorial videos, annotated command outputs, workshop notes, and more for those wanting to learn and improve their skills in Stata, SPSS, SAS, and R. They emphasize applications while explaining the statistical theories behind them. Highly recommended as introductory material to these software.

3. R for Data Science (Hadley Wickham & Garrett Grolemund, 2017)

Wickham and Grolemund's R for Data Science book teaches a select number of indispensable tools for data preparation, visualization, and reporting. Particularly, they demonstrate the dplyr library for transformations, ggplot2 for professional graphics, and R Markdown for presentable documentation. A must-read for anyone working with the R programming language.

4. LibreOffice: The Document Foundation (free open-source equivalent to Microsoft Office)

Microsoft Office is ubiquitous. While its cost is a non-issue for large organizations, for others, however, even its cheapest options are expensive. Fortunately, LibreOffice offers suites that function the same, such as its Writer Document (Word equivalent) and Calc Spreadsheet (Excel equivalent). Notably, the Math Formula suite incorporates a formula editor that makes users be able to type complex mathematical equations at a faster rate than the cumbersome point-and-click method in Word. Additionally, LibreOffice's Access-equivalent Base boasts formal SQL scripting abilities and Wizard functions that guide the database design process. Recommended for students, work-at-home users, and smaller organizations wishing to cut costs.

5. bookdown.org

Bookdown.org is a site containing free online books about R. Notably, the bookdown book teaches you how to create your own books in R with the bookdown package (this book you're reading was created with this package!). Highly recommended for R users of any level, beginner through expert.

About the Author

Hello, I'm Robert Schnitman! I am an independent contractor providing statistical consulting and data analysis services to organizations and individuals. My services include preparing statistical reports, restructuring datasets, and creating visualizations. On the side, I blog primarily about R and data analysis on my website at https://robertschnitman.netlify.app/.
